#### Abstract

In this paper we give a direct proof of the fact that for any schemes of finite type $X, Y$ over a Noetherian scheme $S$ the natural map of presheaves with transfers

$$
\underline{\operatorname{Hom}}\left(\mathbf{Z}_{t r}(X), \mathbf{Z}_{t r}(Y)\right) \rightarrow \underline{\operatorname{Hom}}\left(\mathbf{Z}_{t r}(X) \otimes_{t r} \mathbf{G}_{m}, \mathbf{Z}_{t r}(Y) \otimes_{t r} \mathbf{G}_{m}\right)
$$

is a (weak) $\mathbf{A}^{1}$-homotopy equivalence. As a corollary we deduce that the Tate motive is quasi-invertible in the triangulated categories of motives over perfect fields.

## 1 Introduction

Let $\operatorname{SmCor}(k)$ be the category of finite correspondences between smooth schemes over a field $k$. Denote by $\mathbf{G}_{m}$ the scheme $\mathbf{A}^{1}-\{0\}$. One defines the sheaf with transfers $S_{t}^{1}$ by the condition that $\mathbf{Z}_{t r}\left(\mathbf{G}_{m}\right)=S_{t}^{1} \oplus \mathbf{Z}$ where $\mathbf{Z}$ is split off by the projection to the point and the point 1. For any scheme $Y$ consider the sheaf with transfers $F_{Y}=\underline{H o m}\left(S_{t}^{1}, S_{t}^{1} \otimes \mathbf{Z}_{t r}(Y)\right)$ which maps a smooth scheme $X$ to $\operatorname{Hom}\left(S_{t}^{1} \otimes \mathbf{Z}_{t r}(X), S_{t}^{1} \otimes \mathbf{Z}_{t r}(Y)\right)$. The main result of this paper is Corollary 4.9 which asserts that for any $Y$ the obvious map $\mathbf{Z}_{t r}(Y) \rightarrow F_{Y}$ defines a quasi-isomorphism of singular simplicial complexes

$$
C_{*}\left(\mathbf{Z}_{t r}(Y)\right) \rightarrow C_{*}\left(F_{Y}\right)
$$

as complexes of presheaves i.e. for any $X$ the map of complexes of abelain groups

$$
C_{*}\left(\mathbf{Z}_{t r}(Y)\right)(X) \rightarrow C_{*}\left(F_{Y}\right)(X)
$$

is a quasi-isomorphism. We then deduce from this result the "Cancellation Theorem" for triangulated motives which asserts that if $k$ is a perfect field then for any $K, L$ in $D M_{-}^{e f f}(k)$ the map

$$
\operatorname{Hom}\left(K, K^{\prime}\right) \rightarrow \operatorname{Hom}\left(K(1), K^{\prime}(1)\right)
$$

is bijective.
This result was previously known in two particular situations. For varieties over a field $k$ with resolution of singularities it was proved in [4]. For $K^{\prime}$ being the motivic complex $\mathbf{Z}(n)[m]$ and any field $k$ it was proved in [5]. Both proofs are very long.
The main part of our argument does not use the assumption that we work with smooth schemes over a field and we give it for separated schemes of finite type over a noetherian base. To be able to do it we define in the first section the category of finite correspondences for separated schemes of finite type over a base. The definition is a straightforward generalization of the definition for schemes over a field based on the constructions of [2] and can be skipped. In the second section we define intersection of relative cycles with Cartier divisors and prove the properties of this construction which we need. In the third we prove our main theorem 4.6 and deduce from it the cancellation theorem over perfect fileds 4.10.
In this paper we say "a relative cycle" instead of "an equidimensional relative cycle". All schemes are separated. The letter $S$ is typically reserved for the base scheme which is assumed to be noetherian. All the standard schemes $\mathbf{P}^{1}$, $\mathbf{A}^{1}$ etc. are over $S$. When no confusion is possible we write $X Y$ instead of $X \times{ }_{S} Y$.
I would like to thank Pierre Deligne who explained to me how to compute the length function.

## 2 Finite correspondences

For a scheme $X$ of finite type over a noetherian scheme $S$ we denote by $c(X / S)$ the group of finite relative cycles on $X$ over $S$. In [2] this group was denoted by $c_{\text {equi }}(X / S, 0)$. If $S$ is regular or if $S$ is normal and the characteristic of $X$ is zero, $c(X / S)$ is the free abelian group generated by closed irreducible subsets of $X$ which are finite over $S$ and surjective over a connected component of $S$. For the general definition see [2, after Lemma 3.3.9]. A morphism $f: S^{\prime} \rightarrow S$ defines the pull-back homomorphism $c(X / S) \rightarrow c\left(X S^{\prime} / S^{\prime}\right)$ which we denote by $\operatorname{cycl}(f)$.
For two schemes $X, Y$ of finite type over $S$ we define the group $c(X, Y)$ of finite correspondences from $X$ to $Y$ as $c(X Y / X)$.
Let us recall the following construction from [2, §3.7]. Let $X^{\prime} \rightarrow X \rightarrow S$ be morphisms of finite type, $\mathcal{W}$ a relative cycle on $X^{\prime}$ over $X$ and $\mathcal{Z}$ a relative
cycle on $X$ over $S$. Then one defines a $\operatorname{cycle} \operatorname{Cor}(\mathcal{W}, \mathcal{Z})$ on $X^{\prime}$ as follows. Let $Z_{i}$ be the components of the support of $\mathcal{Z}$ present with multiplicites $n_{i}$ and $e_{i}: Z_{i} \rightarrow X$ the corresponding closed embeddings. Let $e_{i}^{\prime}: Z_{i} \times_{X} X^{\prime} \rightarrow X^{\prime}$ denote the projections. We set

$$
\operatorname{Cor}(\mathcal{W}, \mathcal{Z})=\sum_{i} n_{i}\left(e_{i}^{\prime}\right)_{*} \operatorname{cycl}\left(e_{i}\right)(\mathcal{W})
$$

where $\left(e_{i}^{\prime}\right)_{*}$ is the (proper) push-forward on cycles.
Let $X, Y$ be schemes of finite type over $S$ and

$$
\begin{aligned}
& f \in c(X, Y)=c(X Y / X) \\
& g \in c(Y, Z)=c(Y Z / Y)
\end{aligned}
$$

finite correspondences. Let

$$
\begin{gathered}
p_{X}: X Y \rightarrow Y \\
p_{Y}: X Y Z \rightarrow X Z
\end{gathered}
$$

be the projections. We define the composition $g \circ f$ by the formula:

$$
\begin{equation*}
g \circ f=\left(p_{Y}\right)_{*} \operatorname{Cor}\left(\operatorname{cycl}\left(p_{X}\right)(g), f\right) \tag{2.1}
\end{equation*}
$$

This operation is linear in both arguments and thus defines a homomorphism of abelian groups

$$
c(X, Y) \otimes c(Y, Z) \rightarrow c(X, Z)
$$

The lemma below follows immediately from the definition of $\operatorname{Cor}(-,-)$ and the fact that the (proper) push-forward commutes with the cycl( - ) homomorphisms ([2, Prop. 3.6.2]).

Lemma 2.1 Let $Y \rightarrow X \rightarrow S$ be a sequence of morphisms of finite type, $p:$ $Y \rightarrow Y^{\prime}$ a morphism over $X, \mathcal{Y} \in \operatorname{Cycl}(Y / X, r) \otimes \mathbf{Q}$ and $\mathcal{X} \in \operatorname{Cycl}(X / S, s) \otimes \mathbf{Q}$. Assume that $p$ is proper on the support of $\mathcal{Y}$. Then

$$
p_{*} \operatorname{Cor}(\mathcal{Y}, \mathcal{X})=\operatorname{Cor}\left(p_{*}(\mathcal{Y}, \mathcal{X})\right)
$$

Lemma 2.2 For any $f \in c(X, Y), g \in c(Y, Z), h \in c(Z, T)$ one has

$$
(h \circ g) \circ f=h \circ(g \circ f) .
$$

Proof: Consider the following diagram

where the morphisms are the obvious projections. Note that all the squares are cartesian. We will also use the projection $6: X Z \rightarrow Z$.
We have $f \in c(X Y / X), g \in c(Y Z / Y)$ and $h \in c(Z T / Z)$. The compositions are given by:

$$
\begin{aligned}
& g \circ f=5_{*} \operatorname{Cor}(\operatorname{cycl}(3)(g), f) \\
& h \circ g=2_{*} \operatorname{Cor}(\operatorname{cycl}(1)(h), g)
\end{aligned}
$$

$(h \circ g) \circ f=4_{*} \operatorname{Cor}(\operatorname{cycl}(3)(h \circ g), f)=4_{*} \operatorname{Cor}\left(\operatorname{cycl}(3)\left(2_{*} \operatorname{Cor}(\operatorname{cycl}(1)(h), g)\right), f\right)$
$h \circ(g \circ f)=7_{*} \operatorname{Cor}(\operatorname{cycl}(6)(h), g \circ f)=7_{*} \operatorname{Cor}\left(\operatorname{cycl}(6)(h), 5_{*} \operatorname{Cor}(\operatorname{cycl}(3)(g), f)\right)$
We have:

$$
\begin{aligned}
& 4_{*} \operatorname{Cor}\left(\operatorname{cycl}(3)\left(2_{*} \operatorname{Cor}(\operatorname{cycl}(1)(h), g)\right), f\right)= \\
& =4_{*} \operatorname{Cor}\left(8_{*} \operatorname{cycl}(3) \operatorname{Cor}(\operatorname{cycl}(1)(h), g), f\right)= \\
& =4_{*} 8_{*} \operatorname{Cor}(\operatorname{cycl}(3) \operatorname{Cor}(\operatorname{cycl}(1)(h), g), f)= \\
& =4_{*} 8_{*} \operatorname{Cor}(\operatorname{Cor}(\operatorname{cycl}(1 \circ 9)(h), \operatorname{cycl}(3)(g)), f)
\end{aligned}
$$

where the first equality holds by [2, Prop. 3.6.2], the second by Lemma 2.1 and the third by [2, Th. 3.7.3]. We also have:

$$
\begin{aligned}
& 7_{*} \operatorname{Cor}\left(\operatorname{cycl}(6)(h), 5_{*} \operatorname{Cor}(\operatorname{cycl}(3)(g), f)\right)= \\
= & 7_{*} 9_{*} \operatorname{Cor}(\operatorname{cycl}(6 \circ 5)(h), \operatorname{Cor}(\operatorname{cycl}(3)(g), f))
\end{aligned}
$$

by [2, Lemma 3.7.1]. We conclude that $(h \circ g) \circ f=h \circ(g \circ f)$ by [2, Prop. 3.7.7].

We denote by $\operatorname{Cor}(S)$ the category of finite correspondences whose objects are schemes of finite type over $S$, morphisms are finite correspondences and the composition of morphisms is defined by (2.1).

For a morphism of schemes $f: X \rightarrow Y$ let $\Gamma_{f}$ be its graph considered as an element of $c(X Y / X)$. One verifies easily that $\Gamma_{g f}=\Gamma_{g} \circ \Gamma_{f}$ and we get a functor $S c h / S \rightarrow \operatorname{Cor}(S)$. Below we use the same symbol for a morphism of schemes and its graph considered as a finite correspondence.
The external product of cycles defines pairings

$$
c(X, Y) \otimes c\left(X^{\prime}, Y^{\prime}\right) \rightarrow c\left(X X^{\prime}, Y Y^{\prime}\right)
$$

and one verifies easily using the results of [2] that this pairing extends to a tensor structure on $\operatorname{Cor}(S)$ with $X \otimes Y:=X Y$.

## 3 Intersecting relative cycles with divisors

Let $X$ be a noetherian scheme and $D$ a Cartier divisor on $X$ i.e. a global section of the sheaf $\mathcal{M}^{*} / \mathcal{O}^{*}$. One defines the $\operatorname{cycle} \operatorname{cycl}(D)$ associated with $D$ as follows. Let $U_{i}$ be an open covering of $X$ such that $D_{U_{i}}$ is of the form $f_{i,+} / f_{i,-} \in \mathcal{M}^{*}\left(U_{i}\right)$. Then $\operatorname{cycl}(D)$ is determined by the property that

$$
\operatorname{cycl}(D)_{\mid U_{i}}=\operatorname{cycl}\left(f_{i,+}^{-1}(0)\right)-\operatorname{cycl}\left(f_{i,-}^{-1}(0)\right)
$$

where on the right hand side one considers the cycles associated with closed subschemes ([2, ]). One defines the support of $D$ as the closed subset $\operatorname{supp}(D):=\operatorname{supp}(\operatorname{cycl}(D))$.
We say that a cycle $\mathcal{Z}=\sum n_{i} z_{i}$ on $X$ intersects $D$ properly if the points $z_{i}$ do not belong to $\operatorname{supp}(D)$. Let $Z_{i}$ be the closure of $z_{i}$ considered as a reduced closed subscheme and $e_{i}: Z_{i} \rightarrow X$ the closed embedding. If $\mathcal{Z}$ and $D$ intersect properly we define their intersection $(\mathcal{Z}, D)$ as the cycle

$$
(\mathcal{Z}, D):=\sum n_{i}\left(e_{i}\right)_{*}\left(\operatorname{cycl}\left(e_{i}^{*}(D)\right)\right)
$$

If $p: X \rightarrow S$ is a morphism of finite type and $\mathcal{Z}$ is a relative cycle of relative dimension $d$ over $S$, we say that $D$ intersects $\mathcal{Z}$ properly relative to $p$ (or properly over $S$ ) if the dimension of fibers of $\operatorname{supp}(D) \cap \operatorname{supp}(\mathcal{Z})$ over $S$ is $\leq d-1$. This clearly implies that $\mathcal{Z}$ intersects $D$ properly and $(\mathcal{Z}, D)$ is defined.

Proposition 3.1 Let $p: X \rightarrow S$ be a morphism of finite type, $\mathcal{Z}$ a relative equidimensional cycle of relative dimension $d$ on $X$ over $S$ and $D$ a Cartier divisor on $X$ which intersects $\mathcal{Z}$ properly over $S$. Then:

1. $(\mathcal{Z}, D)$ is a relative cycle of relative dimension $d-1$ over $S$,
2. let $f: S^{\prime} \rightarrow S$ be a morphism, $X^{\prime}=\left(X \times_{S} S^{\prime}\right)_{\text {red }}$ and let $q_{\text {red }}: X^{\prime} \rightarrow X$ be the restriction of the projection to $X^{\prime}$. If $q_{r e d}^{*}(D)$ is well defined then

$$
\begin{equation*}
f^{*}(\operatorname{cycl}(Z), D)=\left(f^{*}(\operatorname{cycl}(Z)), q_{r e d}^{*}(D)\right) \tag{3.1}
\end{equation*}
$$

where $f^{*}$ refers to the pull-back of relative cycles as defined in [2].

Proof: Let $\mathcal{Z}=\sum_{i} n_{i} z_{i}$ where $z_{i}$ are points on the generic fibers of $p$ and $n_{i} \neq 0$. As usually we denote by $\left[z_{i}\right]$ the reduced closed subschemes with generic points $z_{i}$.
Since our problem is local in the Zariski topology on $X$ and additive in $D$ we may assume that $D=D(f)$ where $f \in \mathcal{O}(X)$ is a function on $X$ which is not zero divisor. The condition that $D$ intersects $\mathcal{Z}$ properly over $S$ is equivalent to the condition that for each $i$ and each point $y$ of $S$ the restriction of $f$ to $\left(\left[z_{i}\right] \times{ }_{S} S \operatorname{pec}\left(k_{y}\right)\right)_{\text {red }}$ is not a zero divisor. Localizing around $\left[z_{i}\right]$ we may assume that the restriction of $f$ to $\left(X \times_{S} \operatorname{Spec}\left(k_{y}\right)\right)_{\text {red }}$ is not a zero divisor for any $y$. Under these assumptions $q_{r e d}^{*}(D)$ is well defined for any $f: S^{\prime} \rightarrow S$. The proposition follows now from Lemma 3.2.

Lemma 3.2 Let $Z$ be an integral scheme, $S$ a reduced scheme, $p: Z \rightarrow S$ an equidimensional morphism and $\operatorname{Spec}(k) \xrightarrow{s_{0}} \operatorname{Spec}(R) \xrightarrow{s_{1}} S$ a fat point over a point $s: \operatorname{Spec}(k) \rightarrow S$ of $S$ (see [2, p.23]). Let $Z_{s}=Z \times_{S} \operatorname{Spec}(k)$ and let $q: Z_{s} \rightarrow Z$ be the projection. Let $f \in \mathcal{O}(Z)$ be a function such that the image of $f$ in $\mathcal{O}\left(Z_{s}\right)_{\text {red }}$ is not a zero divisor. Then

$$
\begin{equation*}
\left(s_{0}, s_{1}\right)^{*}(D(f))=\left(\left(s_{0}, s_{1}\right)^{*}(\eta), f \circ q_{r e d}\right) \tag{3.2}
\end{equation*}
$$

where $\eta$ is the generic point of $Z$ considered as a cycle on $Z$ and $q_{\text {red }}$ : $Z_{s, \text { red }} \rightarrow Z$ is the restriction of $q$ to the maximal reduced subscheme of $Z_{s}$.

Proof: Observe first the cycles on both sides of (3.2) are supported in points of codimension 1 of $Z_{s}$. Let $z$ be such a point. We want to show that the multiplicities of the left and right hand sides of (3.2) in $z$ coincide.
To compute $\left(s_{0}, s_{1}\right)^{*}(\eta)$ one considers the surjection $\psi: \mathcal{O}_{Z_{R}} \rightarrow H$ such that $\operatorname{ker}(\psi)$ is supported in the closed fiber of $Z_{R} \rightarrow \operatorname{Spec}(R)$ and $H$ is flat over $R$. Let $p_{j}$ be the minimal prime ideals of $\mathcal{O}_{Z_{s}}$ and $A_{i}=\mathcal{O}_{Z_{s}} / p_{i}$. Then by definition (see [2, Lemma 3.1.2]),

$$
\left(s_{0}, s_{1}\right)^{*}(\eta)=\sum_{j} \text { length }_{A_{j}}\left(q_{0}^{*}(H) \otimes A_{j}\right) p_{j}
$$

Therefore, for a point $z$ of codimension 1 on $Z_{s}$ we have

$$
\begin{gathered}
\operatorname{mlt}_{z}\left(\left(\left(s_{0}, s_{1}\right)^{*}(\eta), f \circ q_{r e d}\right)\right)= \\
=\sum_{j} \operatorname{length}_{A_{j}}\left(q_{0}^{*}(H) \otimes A_{j}\right) \text { length }_{\mathcal{O}_{Z_{s}, z}}\left(\left(A_{j} / f_{j}\right) \otimes \mathcal{O}_{Z_{s}, z}\right)
\end{gathered}
$$

where $f_{j}$ is the restriction of $f \circ q_{\text {red }}$ to $\left[p_{j}\right]$.
Let $F=\mathcal{O}_{Z} / f \mathcal{O}_{Z}$. We have $D(f)=\sum_{i}$ length $_{\mathcal{O}_{z, y_{i}}}\left(F \otimes \mathcal{O}_{Z, y_{i}}\right) y_{i}$ where $y_{i}$ are the generic points of the scheme $Y=f^{-1}(0)$. Let $F_{i}=F \otimes \mathcal{O}_{\left[y_{i}\right]}$. By definition, we have

$$
\left(s_{0}, s_{1}\right)^{*}(D(f))=\sum_{i} \operatorname{length}_{\mathcal{O}_{z, y_{i}}}\left(F \otimes \mathcal{O}_{Z, y_{i}}\right) \operatorname{Cycl}\left(q_{0}^{*}\left(G_{i}\right)\right) .
$$

where $G_{i}$ is a quotient of $q_{1}^{*}\left(F_{i}\right)$ which is flat over $R$ and such that the kernel of the projection $\phi_{i}: q_{1}^{*}\left(F_{i}\right) \rightarrow G_{i}$ is supported in the closed fiber of $Z_{R} \rightarrow \operatorname{Spec}(R)$. Our conditions imply that this cycle is supported in points of codimension 1 of $Z_{s}$ and for such a point $z$ the multiplicity of $\left(s_{0}, s_{1}\right)^{*}(D(f))$ in $z$ equals

$$
\begin{gather*}
m l t_{z}\left(\left(s_{0}, s_{1}\right)^{*}(D(f))\right)= \\
\sum_{i} \text { length }_{\mathcal{O}_{Z, y_{i}}}\left(F \otimes \mathcal{O}_{Z, y_{i}}\right) \text { length }_{\mathcal{O}_{Z_{s}, z}}\left(q_{0}^{*}\left(G_{i}\right) \otimes \mathcal{O}_{Z_{s}, z}\right) \tag{3.3}
\end{gather*}
$$

Let $K_{0}^{\vee}\left(Z_{s}\right)$ be the Grothendieck group of the bounded derived category of complexes of coherent sheaves $Z_{s}$ whose cohomology are supported in codimension $\geq 1$. Then the formula

$$
l_{Z_{s}, z}(M)=\text { length }_{\mathcal{O}_{Z_{s}, z}}\left(M \otimes \mathcal{O}_{Z_{s}, z}\right)
$$

defines an additive functional on this group and we need to show that

$$
\begin{aligned}
l_{Z_{s}, z}\left(\sum_{i} \text { length }_{\mathcal{O}_{z, y_{i}}}\left(F \otimes \mathcal{O}_{Z, y_{i}}\right) q_{0}^{*}\left(G_{i}\right)\right) & = \\
& =l_{Z_{s}, z}\left(\sum_{j} \operatorname{length}_{A_{j}}\left(q_{0}^{*}(H) \otimes A_{j}\right) A_{j} / f_{j}\right)
\end{aligned}
$$

Let $f_{s}$ be the image of $f$ in $\mathcal{O}_{Z_{s}}$ and let $K_{s}=\operatorname{cone}\left(\mathcal{O}_{Z_{s}} \xrightarrow{\cdot f_{s}} \mathcal{O}_{Z_{s}}\right)$. Since $f_{j}$ are not zero divisors, we have $A_{j} / f_{j}=A_{j} \otimes_{\mathbf{L}} K$ and the additivity of length implies that $l_{Z_{s}, z}\left(M \otimes{ }_{\mathbf{L}} K_{s}\right)$ is zero on any $M$ which is supported in codimension $\geq 1$. Since this condition holds for the difference $q_{0}^{*}(H)-\left(\sum_{j}\right.$ length $\left._{A_{j}}\left(q_{0}^{*}(H) \otimes A_{j}\right) A_{j}\right)$ we conclude that

$$
\begin{align*}
& l_{Z_{s}, z}\left(\sum_{j} \text { length }_{A_{j}}\left(q_{0}^{*}(H) \otimes A_{j}\right) A_{j} / f_{j}\right)=l_{Z_{s}, z}\left(q_{0}^{*}(H) \otimes_{\mathbf{L}} K_{s}\right)= \\
& \quad=l_{Z_{s}, z}\left(\mathbf{L} q_{0}^{*}(\operatorname{cone}(H \xrightarrow{f} H))=l_{Z_{s}, z}\left(\operatorname{cone}\left(q_{0}^{*}(H) \xrightarrow{f} q_{0}^{*}(H)\right)\right)\right. \tag{3.4}
\end{align*}
$$

Let $u$ be a generator of the maximal ideal of $R$. Then $\operatorname{ker}\left(\phi_{i}\right)$ and $\operatorname{ker}(\psi)$ are just the $u$-torsion elements in $q_{1}^{*}\left(F_{i}\right)$ and $\mathcal{O}_{Z_{R}}$ respectively. In particular, $G_{i}$ are $H$-modules i.e. $G_{i}=G_{i} \otimes H$. Therefore, both (3.3) and (3.4) are zero if $z$ does not belong to $W_{s}=\operatorname{Spec}\left(q_{0}^{*}(H)\right) \subset Z_{s}$ and for $z \in W_{s}$ we have

$$
\operatorname{mlt}_{z}\left(\left(s_{0}, s_{1}\right)^{*}(D(f))\right)=l_{W_{s}, z}\left(\sum_{i} \operatorname{length}_{\mathcal{O}_{z, y_{i}}}\left(F \otimes \mathcal{O}_{Z, y_{i}}\right) \mathbf{L} q_{W}^{*}\left(h^{*}\left(G_{i}\right)\right)\right)
$$

and

$$
m l t_{z}\left(\left(\left(s_{0}, s_{1}\right)^{*}(\eta), f \circ q_{r e d}\right)\right)=l_{W_{s}, z}\left(\mathbf{L} q_{W}^{*}(\operatorname{cone}(H \xrightarrow[\rightarrow]{f} H))\right)
$$

where $q_{W}: W_{s} \rightarrow \operatorname{Spec}(H)$ and $h: \operatorname{Spec}(H) \rightarrow \operatorname{Spec}\left(Z_{R}\right)$ are the obvious morphisms. We claim that the difference

$$
M=\operatorname{cone}(H \xrightarrow{f} H)-\left(\sum_{i} \text { length }_{\mathcal{O}_{Z, y_{i}}}\left(F \otimes \mathcal{O}_{Z, y_{i}}\right) h^{*}\left(G_{i}\right)\right)
$$

as an element of $K_{0}$ of $H$-modules is supported in points of $\operatorname{Spec}(H)$ of codimension at $\geq 2$ and therefore

$$
l_{W_{s}, z}\left(\mathbf{L} q_{W}^{*}(M)\right)=0
$$

by Lemma 3.4. Indeed, both sides are zero in the generic points of the generic and of the closed fiber. The restriction of $f$ to the generic fiber $Z_{K}$ of $Z_{R}$ is not a zero divisor since the map $q_{K}: Z_{K} \rightarrow Z$ is flat (because $S$ is reduced) and since $Z$ is integral $f$ is not a zero divisor in $\mathcal{O}_{Z}$. Therefore, the generic fiber of cone $(H \xrightarrow{f} H)$ coincides with $q_{K}^{*}(F)$ which, as an element of $K_{0}$, coincides with $\sum_{i}$ length $_{\mathcal{O}_{z, y_{i}}}\left(F \otimes \mathcal{O}_{Z, y_{i}}\right) q_{K}^{*}\left(F_{i}\right)$ up to codimension $\geq 2$.

Lemma 3.3 Let $p: W \rightarrow \operatorname{Spec}(R)$ be a flat morphism such that $R$ is a discrete valuation ring, let $s: \operatorname{Spec}(k) \rightarrow \operatorname{Spec}(R)$ be a morphism whose image is the closed point of $\operatorname{Spec}(R), W_{s}=W \times_{\operatorname{Spec}(R)} \operatorname{Spec}(k)$ and let $q_{W}: W_{s} \rightarrow W$ be the projection. Let further $M$ be a coherent sheaf on $W$ supported in the closed fiber of $p$. Then

$$
\mathbf{L} q_{W}^{*}(M) \cong q_{W}^{*}(M) \oplus q_{W}^{*}(M)[1]
$$

Proof: Let $s=i s^{\prime}$ be the factorization of $s$ where $i: \operatorname{Spec}(R / m) \rightarrow \operatorname{Spec}(R)$ is the closed embedding and $s^{\prime}: \operatorname{Spec}(k) \rightarrow \operatorname{Spec}(R / m)$ a flat morphism and let $q_{W}=q_{i}^{\prime} q^{\prime}$ be the corresponding factorization of $q_{W}$. Then it is sufficient to show that $\mathbf{L} q_{i}^{*}(M) \cong q_{i}^{*}(M) \oplus q_{i}^{*}(M)[1]$. Since $\left(q_{i}\right)_{*}$ is an exact full embedding it is further sufficient to show that $\left(q_{i}\right)_{*} \mathbf{L} q_{i}^{*}(M) \cong\left(q_{i}\right)_{*} q_{i}^{*}(M) \oplus\left(q_{i}\right)_{*} q_{i}^{*}(M)[1]$. The functor $\left(q_{i}\right)_{*} q_{i}^{*}$ is isomorphic to the functor $(-) \otimes B$ where $B=\mathcal{O}_{W} / p^{*}(m)$. Therefore, $\left(q_{i}\right)_{*} \mathbf{L} q_{i}^{*}$ is isomorphic to the functor $(-) \otimes_{\mathbf{F}} B$. Since $R$ is a discrete valuation ring $m$ is a principal ideal. Let $u$ be a generator of $m$. Since $p$ is flat the image of $u$ in $\mathcal{O}_{W}$ is not a zero divisor. Therefore

$$
(-) \otimes_{\mathbf{L}} B=\operatorname{cone}((-) \xrightarrow{u}(-))
$$

If $M$ is supported in the closed fiber of $p$ then $M \otimes B=M$ and the multiplication by $u$ on $M$ equals zero.

Lemma 3.4 Under the assumptions of Lemma 3.3 let $M$ be a coherent sheaf on $W$ supported in codimension $\geq 2$ and let $w$ be a point of codimension 1 on $W_{s}$. Then

$$
\begin{equation*}
\operatorname{length}_{\mathcal{O}_{W_{s}, w}}\left(\mathbf{L} q_{W}^{*}(M) \otimes \mathcal{O}_{W_{s}, w}\right)=0 \tag{3.5}
\end{equation*}
$$

Proof: It is sufficient to show that (3.5) holds for $M=\mathcal{O}_{W} / p$ where $p$ is a prime ideal of codimension $\geq 2$. There are two types of prime ideals satisfying this condition - the ideals lying over the generic point and the ideals lying over the closed point. If $p$ lies over the generic point and has codimension $\geq 2$ then the closed fiber of the corresponding closed subscheme has codimension at least 2 and $\mathbf{L} q_{W}^{*}(M) \otimes \mathcal{O}_{W_{s}, w}=0$ since $w$ is of codimension 1 .
If $p$ lies in the closed fiber an has codimension $\geq 1$ there then $q_{W}^{*}(M)$ has finite length in $w$ and (3.5) follows by additivity of length from Lemma 3.3.

Corollary 3.5 Let $X^{\prime} \xrightarrow{f} X \rightarrow S$ be morphisms of finite type, $\mathcal{Z}$ a relative cycle on $X$ over $S$ and $\mathcal{W}$ a relative cycle on $X^{\prime}$ over $X$ of dimension 0 . Let further $D$ be a Cartier divisor on $X^{\prime}$ which intersects $\mathcal{W}$ properly over $X$. Then $D$ intersects $\operatorname{Cor}(\mathcal{W}, \mathcal{Z})$ properly over $S$ and one has:

$$
\begin{equation*}
(\operatorname{Cor}(\mathcal{W}, \mathcal{Z}), D)=\operatorname{Cor}((\mathcal{W}, D), \mathcal{Z}) \tag{3.6}
\end{equation*}
$$

Proof: It is a straightforward corollary of the definition of $\operatorname{Cor}(-,-)$ and (3.1).

Lemma 3.6 Let $f: X^{\prime} \rightarrow X$ be a morphism of schemes of finite type over $S$, $\mathcal{Z}$ a relative cycle on $X^{\prime}$ such that $f$ is proper on $\operatorname{supp}(\mathcal{Z})$ and $D$ a Cartier divisor on $X$. Assume that $f^{*}(D)$ is defined and $\mathcal{Z}$ intersects $f^{*}(D)$ properly over $S$. Then $f_{*}(\mathcal{Z})$ intersects $D$ properly over $S$ and one has:

$$
\begin{equation*}
f_{*}\left(\mathcal{Z}, f^{*}(D)\right)=\left(f_{*}(\mathcal{Z}), D\right) \tag{3.7}
\end{equation*}
$$

Proof: Let $d$ be the relative dimension of $\mathcal{Z}$ over $S$. To see that $f_{*}(\mathcal{Z})$ intersects $D$ properly over $S$ we need to check that the dimension of the fibers of $\operatorname{supp}(D) \cap \operatorname{supp}\left(f_{*}(\mathcal{Z})\right)$ over $S$ is $\leq d-1$. This follows from our assumption and the inclusion

$$
\begin{gathered}
\operatorname{supp}(D) \cap \operatorname{supp}\left(f_{*}(\mathcal{Z})\right) \subset \operatorname{supp}(D) \cap f(\operatorname{supp}(\mathcal{Z}))= \\
=f\left(f^{-1}(\operatorname{supp}(D)) \cap \operatorname{supp}(\mathcal{Z})\right)=f\left(\operatorname{supp}\left(f^{*}(D)\right) \cap \operatorname{supp}(\mathcal{Z})\right)
\end{gathered}
$$

To verify (3.7) it is sufficient to consider the situation locally around the generic points of $f\left(\operatorname{supp}\left(f^{*}(D)\right) \cap \operatorname{supp}(\mathcal{Z})\right)$. Therefore we may assume that $D=D(g)$ is the divisor of a regular function $g$ and $\mathcal{Z}=z$ is just one point with the closure $Z$. Replacing $X^{\prime}$ by $Z$ and $X$ by $f(Z)$ we may assume that $X, X^{\prime}$ are integral, $f$ is surjective and $X$ is local of dimension 1. Let $A=\mathcal{O}(X)$, $B=\mathcal{O}\left(X^{\prime}\right)$. Consider the function $l_{g}: M \mapsto l_{A}\left(M \otimes^{L} A / g\right)$ on $K_{0}(A-\bmod )$. This function vanishes on modules with the support in the closed point which implies that

$$
l_{g}(B)=\operatorname{deg}(f) l_{g}(A)=\operatorname{deg}(f) l_{A}(A / g)
$$

On the other hand $l_{g}(A)=l_{A}\left(B /\left(f^{*}(g)\right)\right)$. Let $x_{i}^{\prime}$ be the closed points of $X^{\prime}$, $k_{i}^{\prime}$ their residue fields and $k$ the residue field of the closed point of $X$. Let further $M_{i}$ be the part of $B /\left(f^{*}(g)\right)$ supported in $x_{i}^{\prime}$. One can easily see that $l_{A}\left(B /\left(f^{*}(g)\right)\right)=\sum_{i}\left[k_{i}^{\prime}: k\right] l_{B}\left(M_{i}\right)$. Combining our equalities we get:

$$
\begin{equation*}
\operatorname{deg}(f) l_{A}(A / g)=\sum_{i}\left[k_{i}^{\prime}: k\right] l_{B}\left(M_{i}\right) \tag{3.8}
\end{equation*}
$$

which is equivalent to (3.7).

## 4 Cancellation theorem

Consider a finite correspondence

$$
\mathcal{Z} \in c\left(\mathbf{G}_{m} X, \mathbf{G}_{m} Y\right)=c\left(\mathbf{G}_{m} X \mathbf{G}_{m} Y / \mathbf{G}_{m} X\right)
$$

Let $f_{1}, f_{2}$ be the projections to the first and the second copy of $\mathbf{G}_{m}$ respectively and let $g_{n}$ denote the rational function $\left(f_{1}^{n+1}-1\right) /\left(f_{1}^{n+1}-f_{2}\right)$ on $\mathbf{G}_{m} X \mathbf{G}_{m} Y$.

Lemma 4.1 For any $\mathcal{Z}$ there exists $N$ such that for all $n \geq N$ the divisor of $g_{n}$ intersects $\mathcal{Z}$ properly over $X$ and the cycle $\left(\mathcal{Z}, D\left(g_{n}\right)\right)$ is finite over $X$.
Proof: Let $\bar{f}_{1} \times \bar{q}: \bar{C} \rightarrow \mathbf{P}^{1} X$ be a finite morphism which extends the projection $\operatorname{supp}(\mathcal{Z}) \rightarrow \mathbf{G}_{m} X$. Let $N$ be an integer such that the rational function $\bar{f}_{1}^{N} / f_{2}$ is regular in a neighborhood of $\bar{f}_{1}^{-1}(0)$ and the rational function $f_{2} / \bar{f}_{1}^{N}$ is regular in a neighborhood of $\bar{f}_{1}^{-1}(\infty)$. Then for any $n \geq N$ one has:

1. the restriction of $g_{n} f_{2}$ to $\operatorname{supp}(\mathcal{Z})$ is regular on a neighborhood of $\bar{f}_{1}^{-1}(0)$ and equals 1 on $\bar{f}_{1}^{-1}(0)$
2. the restriction of $g_{n}$ to $\operatorname{supp}(\mathcal{Z})$ is regular a neighborhood of $\bar{f}_{1}^{-1}(\infty)$ and equals 1 on $\bar{f}_{1}^{-1}(\infty)$

Conditions (1),(2) imply that the divisor of $g_{n}$ intersects $\mathcal{Z}$ properly over $X$ and that the relative cycle $\left(\mathcal{Z}, D\left(g_{n}\right)\right)$ is finite over $X$.

If $\left(\mathcal{Z}, D\left(g_{n}\right)\right)$ is defined as a finite relative cycle we let $\rho_{n}(\mathcal{Z}) \in c(X, Y)$ denote the projection of $\left(\mathcal{Z}, D\left(g_{n}\right)\right)$ to $X Y$.
Remark 4.2 Note that we can define a finite correspondence $\rho_{g}(\mathcal{Z}): X \rightarrow Y$ for any function $g$ satisfying the conditions (1),(2) in the same way as we defined $\rho_{n}=\rho_{g_{n}}$. In particular, if $n$ and $m$ are large enough then the function $t g_{n}+(1-t) g_{m}$ defines a finite correspondence $h=h_{n, m}: X \mathbf{A}^{1} \rightarrow Y$ such that $h_{\mid X \times\{0\}}=\rho_{m}(\mathcal{Z})$ and $h_{\mid X \times\{1\}}=\rho_{n}(\mathcal{Z})$, i.e. we get a canonical $\mathbf{A}^{1}$-homotopy from $\rho_{m}(\mathcal{Z})$ to $\rho_{n}(\mathcal{Z})$.

Lemma 4.3 (i) For a finite correspondence $\mathcal{W}: X \rightarrow Y$ and any $n \geq 1$ one has $\rho_{n}\left(I d_{\mathbf{G}_{m}} \otimes \mathcal{W}\right)=\mathcal{W}$
(ii) Let $e_{X}$ be the composition $\mathbf{G}_{m} X \xrightarrow{p r} X \xrightarrow{\{1\} \times I d} \mathbf{G}_{m} X$. Then $\rho_{n}\left(e_{X}\right)=0$ for any $n \geq 0$.

Proof: The cycle on $\mathbf{G}_{m} X \mathbf{G}_{m} Y$ over $\mathbf{G}_{m} X$ which represents $I d_{\mathbf{G}_{m}} \otimes \mathcal{W}$ is $\Delta_{*}\left(\mathbf{G}_{m} \times \mathcal{W}\right)$ where $\Delta$ is the diagonal embedding $\mathbf{G}_{m} X Y \rightarrow \mathbf{G}_{m} X \mathbf{G}_{m} Y$. The cycle $\left(\Delta_{*}\left(\mathbf{G}_{m} \times \mathcal{W}\right), g_{n}\right)$ is $\Delta_{*}(D \otimes \mathcal{W})$ where $D$ is the divisor of the function $\left(t^{n+1}-1\right) /\left(t^{n+1}-t\right)$ on $\mathbf{G}_{m}$. The push-forward of $\Delta_{*}(D \otimes \mathcal{W})$ to $X Y$ is the cycle $\operatorname{deg}(D) \mathcal{W}$. Since $\operatorname{deg}(D)=1$ we get the first statement of the lemma.
The cycle $\mathcal{Z}$ on $\mathbf{G}_{m} X \mathbf{G}_{m} X$ representing $e_{X}$ is the image of the embedding $\mathbf{G}_{m} X \rightarrow \mathbf{G}_{m} X \mathbf{G}_{m} X$ which is diagonal on $X$ and of the form $t \mapsto(t, 1)$ on $\mathbf{G}_{m}$. This shows that the restriction of $g_{n}$ to $\operatorname{supp}(\mathcal{Z})$ equals 1 and $\left(\mathcal{Z}, D\left(g_{n}\right)\right)=0$.

Lemma 4.4 Let $\mathcal{Z}: \mathbf{G}_{m} X \rightarrow \mathbf{G}_{m} Y$ be a finite correspondence such that $\rho_{n}(\mathcal{Z})$ is defined. Then for any finite correspondence $\mathcal{W}: X^{\prime} \rightarrow X$, $\rho_{n}\left(\mathcal{Z} \circ\left(I d_{\mathbf{G}_{m}} \otimes \mathcal{W}\right)\right)$ is defined and one has

$$
\begin{equation*}
\rho_{n}\left(\mathcal{Z} \circ\left(I d_{\mathbf{G}_{m}} \otimes \mathcal{W}\right)\right)=\rho_{n}(\mathcal{Z}) \circ \mathcal{W} \tag{4.1}
\end{equation*}
$$

Proof: Let us show that (4.1) holds. In the process it will become clear that the left hand side is defined. We can write $\rho_{n}(\mathcal{Z}) \circ \mathcal{W}$ as the composition

$$
X^{\prime} \xrightarrow{\mathcal{W}} X \xrightarrow{\left(\mathcal{Z}, D\left(g_{n}\right)\right)} \mathbf{G}_{m} \mathbf{G}_{m} Y \xrightarrow{p r} Y
$$

and $\rho_{n}\left(\mathcal{Z} \circ\left(I d_{\mathbf{G}_{m}} \otimes \mathcal{W}\right)\right)$ as the composition

$$
X^{\prime} \xrightarrow{\mathcal{Y}} \mathbf{G}_{m} \mathbf{G}_{m} Y \xrightarrow{p r} Y
$$

where $\mathcal{Y}=\left(\mathcal{Z} \circ\left(I d_{\mathbf{G}_{m}} \otimes \mathcal{W}\right), D\left(g_{n}\right)\right)$. Consider the diagram

where the arrows are the obvious projections. If we consider $\mathcal{Z}$ as a cycle of dimension 1 over $X$ then the cycle $\mathcal{Z} \circ\left(I d_{\mathbf{G}_{m}} \otimes \mathcal{W}\right)$, considered as a cycle over $X^{\prime}$, is $\left(p_{1}\right)_{*} \operatorname{Cor}\left(\operatorname{cycl}\left(p_{2}\right)(\mathcal{Z}), \mathcal{W}\right)$ and we have

$$
\begin{gathered}
\left(\left(p_{1}\right)_{*} \operatorname{Cor}\left(\operatorname{cycl}\left(p_{2}\right)(\mathcal{Z}), \mathcal{W}\right), D\left(g_{n}\right)\right)= \\
=\left(p_{1}\right)_{*}\left(\operatorname{Cor}\left(\operatorname{cycl}\left(p_{2}\right)(\mathcal{Z}), \mathcal{W}\right), D\left(g_{n}\right)\right)=\left(p_{1}\right)_{*} \operatorname{Cor}\left(\left(\operatorname{cycl}\left(p_{2}\right)(\mathcal{Z}), D\left(g_{n}\right)\right), \mathcal{W}\right)= \\
=\left(p_{1}\right)_{*} \operatorname{Cor}\left(\operatorname{cycl}\left(p_{2}\right)\left(\mathcal{Z}, D\left(g_{n}\right)\right), \mathcal{W}\right)
\end{gathered}
$$

where the first equality holds by (3.7), the second by (3.6) and the third by (3.1).

The last expression represents the composition $\mathcal{W} \circ\left(\mathcal{Z}, D\left(g_{n}\right)\right)$ and we conclude that

$$
\rho_{n}(\mathcal{Z}) \circ \mathcal{W}=\rho_{n}\left(\mathcal{Z} \circ\left(I d_{\mathbf{G}_{m}} \otimes \mathcal{W}\right)\right)
$$

Lemma 4.5 Let $\mathcal{Z}: \mathbf{G}_{m} X \rightarrow \mathbf{G}_{m} Y$ be a finite correspondence such that $\rho_{n}(\mathcal{Z})$ is defined. Then for any morphism of schemes $f: X^{\prime} \rightarrow Y^{\prime}, \rho_{n}(\mathcal{Z} \otimes f)$ is defined and one has

$$
\begin{equation*}
\rho_{n}(\mathcal{Z} \otimes f)=\rho_{n}(\mathcal{Z}) \otimes f \tag{4.2}
\end{equation*}
$$

Proof: Consider the diagram

where $p_{1}$ is defined by the embedding $X^{\prime} \xrightarrow{f \times I d} X^{\prime} Y^{\prime}$ and the rest of the morphisms are the obvious projections. Consider $\mathcal{Z}$ as a cycle over $X$. Then $\rho_{n}(\mathcal{Z} \otimes f)$ is given by the composition

$$
\mathbf{G}_{m} X X^{\prime} \xrightarrow{\mathcal{Y}_{1}} \mathbf{G}_{m} \mathbf{G}_{m} Y \xrightarrow{p r} Y Y^{\prime}
$$

where $\mathcal{Y}_{1}=\left(\left(p_{1}\right)_{*} \operatorname{cycl}\left(p_{2}\right)(\mathcal{Z}), g_{n}\right)$ and $\rho_{n}(\mathcal{Z}) \otimes f$ by the composition

$$
\mathbf{G}_{m} X X^{\prime} \xrightarrow{\mathcal{Y}_{2}} \mathbf{G}_{m} \mathbf{G}_{m} Y \xrightarrow{p r} Y Y^{\prime}
$$

where $\mathcal{Y}_{2}=\left(p_{1}\right)_{*}\left(\operatorname{cycl}\left(p_{2}\right)\left(\left(\mathcal{Z}, g_{n}\right)\right)\right)$. The equality $\mathcal{Y}_{1}=\mathcal{Y}_{2}$ follows from (3.7) and (3.1).

For our next result we need to use presheaves with transfers. A presheaf with transfers on $S c h / S$ is an additive contravariant functor from $\operatorname{Cor}(S)$ to the category of abelian groups. For $X$ in $S c h / S$ we let $\mathbf{Z}_{t r}(X)$ denote the functor represented by $X$ on $\operatorname{Cor}(S)$. One defines tensor product of presheaves with transfers in the usual way such that $\mathbf{Z}_{t r}(X) \otimes \mathbf{Z}_{t r}(Y)=\mathbf{Z}_{t r}(X \times Y)$. To simplify notations we will write $X$ instead of $\mathbf{Z}_{t r}(X)$ and identify morphisms $\mathbf{Z}_{t r}(X) \rightarrow \mathbf{Z}_{t r}(Y)$ with finite correspondences $X \rightarrow Y$. Note in particular that $\mathbf{G}_{m}$ denotes the presheaf with transfers $\mathbf{Z}_{t r}\left(\mathbf{G}_{m}\right)$ not the presheaf with transfers represented by $\mathbf{G}_{m}$ as a scheme. To preserve compatibility with the notation $X Y$ for the product of $X$ and $Y$ we write $F G$ for the tensor product of presheaves with transfers $F$ and $G$.
Let $S_{t}^{1}$ denote the presheaf with transfers $\operatorname{ker}\left(\mathbf{G}_{m} \rightarrow S\right)$. We consider it as a direct summand of $\mathbf{G}_{m}$ with respect to the projection $I d-e$ where $e$ is defined by the composition $\mathbf{G}_{m} \rightarrow S \xrightarrow{1} \mathbf{G}_{m}$. In the following theorem we let $f \cong g$ denote that the morphisms $f$ and $g$ are $\mathbf{A}^{1}$-homotopic.

Theorem 4.6 Let $F$ be a presheaf with transfers such that there is an epimorphism $X \rightarrow F$ for a scheme $X$. Let $\phi: S_{t}^{1} \otimes F \rightarrow S_{t}^{1} Y$ be a morphism. Then there exists a unique up to an $\mathbf{A}^{1}$-homotopy morphism $\rho(\phi): F \rightarrow Y$ such that $I d_{S_{t}^{1}} \otimes \rho(\phi) \cong \phi$.

Proof: Let us fix an epimorphism $p: X \rightarrow F$. Then the morphism $\phi$ defines a finite correspondence $\mathcal{Z}: \mathbf{G}_{m} X \rightarrow \mathbf{G}_{m} Y$ and for $n$ sufficiently large we may consider $\rho_{n}(\mathcal{Z}): X \rightarrow Y$. Lemma 4.4 implies immediately that $\rho_{n}(\mathcal{Z})$ vanishes on $\operatorname{ker}(p)$ and therefore it defines a morphism $\rho_{n}(\phi): F \rightarrow X$.

Consider a morphism $\phi$ of the form $I d_{S_{t}^{1}} \otimes \psi$. Then $\mathcal{Z}$ is of the form $\left(I d_{\mathbf{G}_{m}}-e\right) \otimes \mathcal{W}$ where $\mathcal{W}: X \rightarrow Y$ corresponds to $\psi$. By Lemma 4.3 we have $\rho_{n}(\mathcal{Z})=\mathcal{W}$ and therefore $\rho_{n}\left(I d_{S_{t}^{1}} \otimes \psi\right)=\psi$ for any $n \geq 1$. If $\rho, \rho^{\prime}$ are two morphims such that $I d_{S_{t}^{1}} \otimes \rho \cong \phi$ and $I d_{S_{t}^{1}} \otimes \rho^{\prime} \cong \phi$ then for a sufficiently large $n$ we have

$$
\rho=\rho_{n}\left(I d_{S_{t}^{1}} \otimes \rho\right) \cong \rho_{n}\left(I d_{S_{t}^{1}} \otimes \rho^{\prime}\right)=\rho^{\prime}
$$

This implies the uniqueness part of the theorem.
To prove the existence let us show that for a sufficiently large $n$ one has $I d_{S_{t}^{1}} \otimes \rho_{n}(\phi) \cong \phi$. Let $\widetilde{\phi}$ be the morphism $\mathbf{G}_{m} F \rightarrow \mathbf{G}_{m} Y$ defined by $\phi$ and let

$$
\widetilde{\phi}^{*}: F \mathbf{G}_{m} \rightarrow Y \mathbf{G}_{m}
$$

be the morphism obtained from $\widetilde{\phi}$ by the obvious permutation.
Lemma 4.7 The morphisms $\widetilde{\phi} \otimes\left(I d_{\mathbf{G}_{m}}-e\right)$ and $\left(I d_{\mathbf{G}_{m}}-e\right) \otimes \widetilde{\phi^{*}}$ are $\mathbf{A}^{1}$ homotopic.
Proof: One can easily see that these two morphisms are obtained from the morphisms

$$
\phi \otimes I d_{S_{t}^{1}}, I d_{S_{t}^{1}} \otimes \phi^{*}: S_{t}^{1} F S_{t}^{1} \rightarrow S_{t}^{1} Y S_{t}^{1}
$$

by using the standard direct sum decomposition. One can see further that $\phi \otimes I d_{S_{t}^{1}}=\sigma_{Y}\left(I d_{S_{t}^{1}} \otimes \phi^{*}\right) \sigma_{F}$ where $\sigma_{F}$ and $\sigma_{Y}$ are the permutations of the two copies of $S_{t}^{1}$ in $S_{t}^{1} F S_{t}^{1}$ and $S_{t}^{1} Y S_{t}^{1}$ respectively. Lemma 4.8 below implies now that $\phi \otimes I d_{S_{t}^{1}} \cong I d_{S_{t}^{1}} \otimes \phi^{*}$.

Lemma 4.8 The permutation on $S_{t}^{1} S_{t}^{1}$ is $\mathbf{A}^{1}$-homotopic to $\{-1\} I d \otimes$ Id where $\{-1\}: S_{t}^{1} \rightarrow S_{t}^{1}$ is defined by the morphism $\mathbf{G}_{m} \xrightarrow{x \mapsto x^{-1}} \mathbf{G}_{m}$.
Proof: The same arguments as the ones used in [1, p.142] show that for any scheme $X$ and any pair of invertible functions $f, g$ on $X$ the morphism $X \xrightarrow{f \otimes g}$ $S_{t}^{1} S_{t}^{1}$ is $\mathbf{A}^{1}$-homotopic to the morphism $g \otimes f^{-1}$. This implies immediately that the permutation on $S_{t}^{1} S_{t}^{1}$ is $\mathbf{A}^{1}$-homotopic to the morphism $I d \otimes(\{-1\} I d)$ where $\{-1\} I d: S_{t}^{1} \rightarrow S_{t}^{1}$ is the morphism defined by the map $\mathbf{G}_{m} \xrightarrow{x \mapsto x^{-1}} \mathbf{G}_{m}$.

For a sufficiently large $n$ we have

$$
\rho_{n}\left(\phi \otimes\left(I d_{\mathbf{G}_{m}}-e\right)\right)=\rho_{n}(\phi) \otimes\left(I d_{\mathbf{G}_{m}}-e\right)
$$

by Lemma 4.5. On the other hand

$$
\rho_{n}\left(\left(I d_{\mathbf{G}_{m}}-e\right) \otimes \phi^{*}\right)=\phi^{*}
$$

by Lemma 4.3. By Lemma 4.7 we conclude that

$$
\phi^{*} \cong \rho_{n}(\phi) \otimes\left(I d_{\mathbf{G}_{m}}-e\right)
$$

which is equivalent to $I d_{S_{t}^{1}} \otimes \rho_{n}(\phi) \cong \phi$. Theorem 4.6 is proved.

Corollary 4.9 Denote by $F_{Y}$ the presheaf

$$
X \mapsto \operatorname{Hom}\left(S_{t}^{1} X, S_{t}^{1} Y\right)
$$

and consider the obvious map $Y \rightarrow F_{Y}$. Then for any $X$ the corresponding map of complexes of abelian groups

$$
C_{*}(Y)(X) \rightarrow C_{*}\left(F_{Y}\right)(X)
$$

is a quasi-isomorphism

Proof: Let $\Delta^{n} \cong \mathbf{A}^{n}$ be the standard algebraic simplex and $\partial \Delta^{n}$ the subpresheaf in $\Delta^{n}$ which is the union of the images of the face maps $\Delta^{n-1} \rightarrow \Delta^{n}$. Then the n-th homology group of the complex $C_{*}(F)(X)$ for any $F$ is the group of homotopy classes of maps from $X \otimes\left(\Delta^{n} / \partial \Delta^{n}\right)$ to $F$. Our result now follows directly from 4.6.

Corollary 4.10 Let $k$ be a perfect field. Then for any $K, L$ in $D M_{-}^{e f f}(k)$ the map $\operatorname{Hom}(K, L) \rightarrow \operatorname{Hom}(K(1), L(1))$ is a bijection.

Proof: Since $D M_{-}^{e f f}$ is generated by objects of the form $X$ it is enough to check that for smooth schemes $X, Y$ over $k$ and $n \in \mathbf{Z}$ one has

$$
H o m\left(S_{t}^{1} X, S_{t}^{1} Y[n]\right)=H o m(X, Y[n])
$$

By Corollary 4.9 we know that the map

$$
Y \rightarrow F_{Y}=\underline{\operatorname{Hom}}\left(S_{t}^{1}, S_{t}^{1} Y\right)
$$

is an isomorphism in $D M$. Let us show now that for any sheaf with transfers $F$ and any $X$ one has

$$
\begin{equation*}
\operatorname{Hom}_{D M}\left(S_{t}^{1} X, F[n]\right)=\operatorname{Hom}_{D M}\left(X, \underline{\operatorname{Hom}}\left(S_{t}^{1}, F\right)[n]\right) \tag{4.3}
\end{equation*}
$$

The left hand side of (4.3) is the hypercohomology group $\mathbf{H}^{n}\left(\mathbf{G}_{m} X, C_{*}(F)\right)$ modulo the subgroup $\mathbf{H}^{n}\left(X, C_{*}(F)\right)$. The right hand side is the hypercohomology group $\mathbf{H}^{n}\left(X, C_{*} \underline{\operatorname{Hom}}\left(\mathbf{G}_{m}, F\right)\right)$ modulo similar subgroup. Let $p: \mathbf{G}_{m} X \rightarrow X$ be the projection. It is easy to see that (4.3) asserts that $\mathbf{R} p_{*}\left(C_{*}(F)\right) \cong C_{*}\left(p_{*}(F)\right)$. There is a spectral sequence which converges to the cohomology sheaves of $\mathbf{R} p_{*}\left(C_{*}(F)\right)$ and starts with the higher direct images $R^{i} p_{*}\left(\underline{H}^{j}\left(C_{*}(F)\right)\right)$. We need to verify that $R^{i} p_{*}\left(\underline{H}^{j}\left(C_{*}(F)\right)\right)=0$ for $i>0$ and that $p_{*}\left(\underline{H}^{j}\left(C_{*}(F)\right)\right)=\underline{H}^{j}\left(C_{*}\left(p_{*}(F)\right)\right)$. Both statements follow from [3, Prop. 4.34, p.124] and the comparison of Zariski and Nisnevich cohomology for homotopy invariant presheaves with transfers.
